# Markov Decision Process (MDP)

 $M = (S, A, T, R, \gamma)$ 

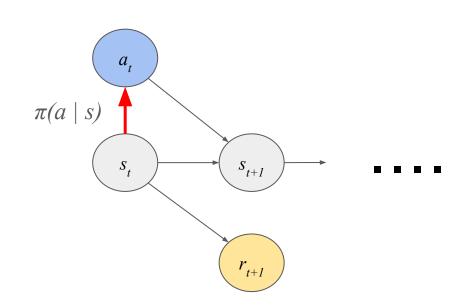

S: set of states

A: set of actions

*T*: transition function

R: reward function

 $\gamma$ : discount factor

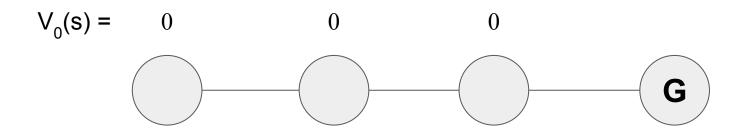

## Planning Problem

Compute the optimal value for every state

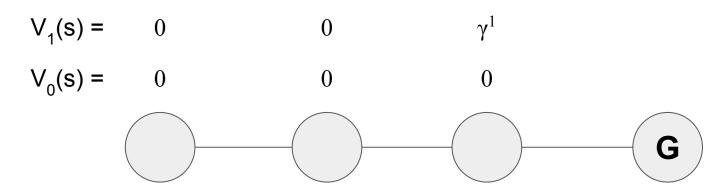

**Definition 1** (Value-Planning Problem): **Given** an MDP  $M = \langle \mathcal{S}, \mathcal{A}, R, T, \gamma \rangle$  and a non-negative real-value  $\epsilon$ , **return** a value function, V such that  $|V(s) - V^*(s)| < \epsilon$  for all  $s \in \mathcal{S}$ .

$$V^*(s) = \gamma^3 \qquad \gamma^2 \qquad \gamma^1$$

We focus on value iteration algorithm

We focus on value iteration algorithm

We focus on value iteration algorithm

$$V_{2}(s) = 0$$
  $\gamma^{2}$   $\gamma^{1}$ 
 $V_{1}(s) = 0$   $0$   $\gamma^{1}$ 
 $V_{0}(s) = 0$   $0$   $0$ 
**G**

We focus on value iteration algorithm

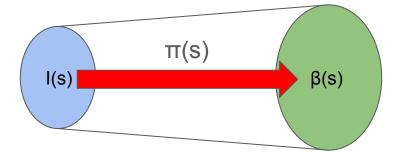

$$V_{3}(s) = \gamma^{3}$$
  $\gamma^{2}$   $\gamma^{1}$   $V_{2}(s) = 0$   $\gamma^{2}$   $\gamma^{1}$   $V_{1}(s) = 0$   $0$   $\gamma^{1}$   $V_{0}(s) = 0$   $0$   $0$   $O$ 

## Options (Sutton et al. 1999)

```
I(s) := initiation set
```

 $\beta(s) := termination probability$ 

 $\pi(s) := policy$ 

We assume the optimal policy is given

Our objective is to speedup the value iteration algorithm by adding options to the primitive actions

$$V_{i+1}(s) = \max_{o \in A \cup \mathcal{O}} \left( R_{\gamma}(s, o) + \sum_{s' \in S} T_{\gamma}(s, o, s') V_i(s') \right)$$

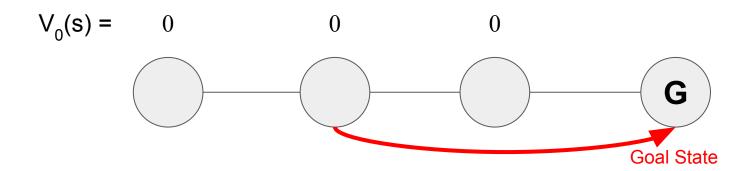

Our objective is to speedup the value iteration algorithm by adding options to the primitive actions

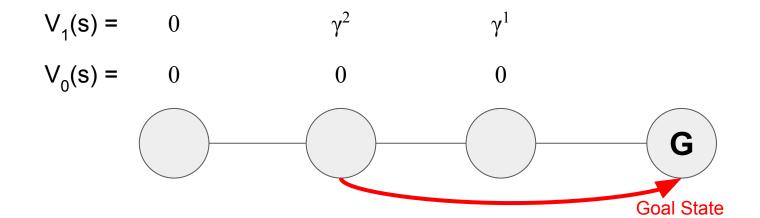

$$V_{i+1}(s) = \max_{o \in A \cup \mathcal{O}} \left( R_{\gamma}(s, o) + \sum_{s' \in S} T_{\gamma}(s, o, s') V_i(s') \right)$$

We assume that the model of the options are given to the agent

$$T_{\gamma}(s, o, s') = \sum_{t=0}^{\infty} \gamma^{t} \Pr(s_{t} = s', \beta(s_{t}) \mid s, o).$$

$$R_{\gamma}(s, o) = \mathbb{E} \left[ r_{1} + \gamma r_{2} + \ldots + \gamma^{k-1} r_{k} \mid s, o \right]$$

→It needs fewer iterations than just primitive actions!

$$V_{2}(s) = \gamma^{3} \qquad \gamma^{2} \qquad \gamma^{1}$$

$$V_{1}(s) = 0 \qquad \gamma^{2} \qquad \gamma^{1}$$

$$V_{0}(s) = 0 \qquad 0$$

$$Goal State$$

## Objective Functions

- 1. Number of Iterations: *L(O)*
- 2. Number of options: |O|

**Definition 3**  $(L(\mathcal{O}))$ : The number of iterations  $L(\mathcal{O})$  of a value-iteration algorithm using option set  $\mathcal{A} \cup \mathcal{O}$ , with  $\mathcal{O}$  a non-empty set of options, is the smallest b at which  $|V_b(s) - V^*(s)| < \epsilon$  for all  $s \in \mathcal{S}$ .

## Two Optimization Problems: MIMO and MOMI

- 1. Number of Iterations: L(O)
- 2. Number of options: |O|

**MIMO**: Minimize L(O) subject to  $|O| \le k$ 

**MOMI**: Minimize |O| subject to  $L(O) \leq L$ 

## Two Optimization Problems: MIMO and MOMI

- 1. Number of Iterations: L(O)
- 2. Number of options: |O|

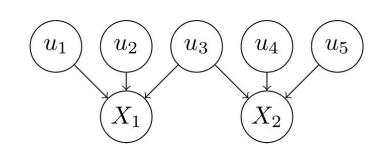

**MIMO**: Minimize L(O) subject to  $|O| \le k$ 

**MOMI**: Minimize |O| subject to  $L(O) \leq L$ 

→Both MIMO and MOMI are NP-hard.

Proof: Reduction from the set cover decision problem.

Reduction from the set cover decision problem.

Set Cover Decision Problem:

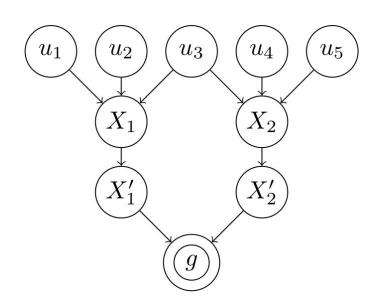

A set of elements  $\{u_1, u_2, ...\} = \mathcal{U}$ 

A set of subsets  $\mathcal{X} = \{X_1, X_2, ...\}, X_i \subseteq \mathcal{U}$ 

Find a set of subsets  $\mathcal{C} \subseteq \mathcal{X}$  of size  $\mathbf{k}$ , such that  $\bigcup_{X \in \mathcal{C}} X = \mathcal{U}$ 

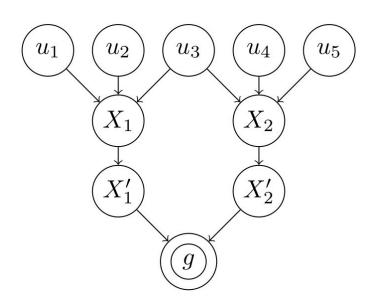

#### Reduction:

1. Construct a shortest path problem

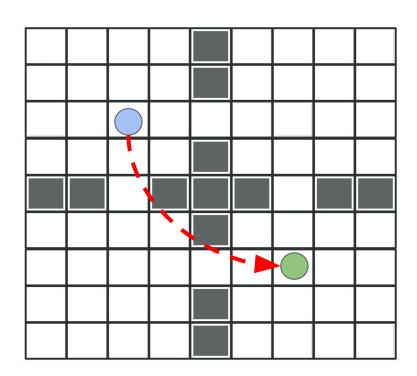

#### Reduction:

- 1. Construct a shortest path problem
- 2. Restrict to point options

# **Point Option**

From one state to one state

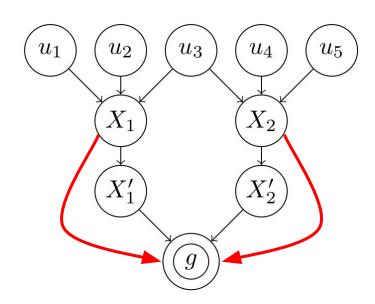

: Initiation State: *I*(s)

 $\blacksquare$ : Termination State:  $\beta$ (s)

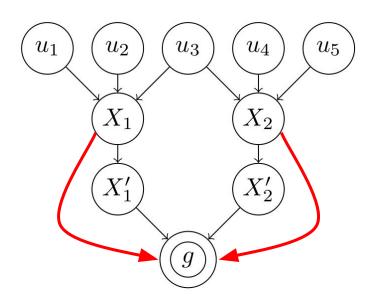

#### Reduction:

- Construct a shortest path problem
- 2. Restrict to point options
- 3. Reduce to a decision problem of finding a set of point options such that  $|O| \le k$  and  $L(O) \le 2$

#### Reduction:

- Construct a shortest path problem
- 2. Restrict to point options
- 3. Reduce to a decision problem of finding a set of point options such that  $|O| \le k \text{ and } L(O) \le 2$
- MIMO / MOMI are optimization versions of the above problem, thus NP-hard.

## Finding Optimal Behavioral Abstraction is NP-Hard

Given a <u>single deterministic shortest-path problem</u>, finding an optimal set of <u>point options</u> is NP-hard

## Finding Optimal Behavioral Abstraction is NP-Hard

Given a set of MDPs, finding a set of options which minimizes an expected (or maximum) planning time is NP-hard.

#### **Definition 10** (MIMO $_{multi}$ ):

**Given** A distribution of MDPs D,  $\mathcal{O}' \subseteq \mathcal{O}_{all}$ , a nonnegative real-value  $\epsilon$ , and an integer  $\ell$ , **return**  $\mathcal{O}$  that minimizes  $E_{M \sim D}[L_M(\mathcal{O})]$  such that  $\mathcal{O} \subseteq \mathcal{O}'$  and  $|\mathcal{O}| < k$ .

# Finding Optimal Behavioral Abstraction is NP-Hard

Given a set of MDPs, finding a set of options which minimizes an expected (or maximum) planning time is NP-hard.

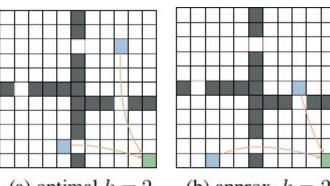

#### **Definition 10** (MIMO $_{multi}$ ):

**Given** A distribution of MDPs D,  $\mathcal{O}' \subseteq \mathcal{O}_{all}$ , a nonnegative real-value  $\epsilon$ , and an integer  $\ell$ , **return**  $\mathcal{O}$  that minimizes  $E_{M \sim D}[L_M(\mathcal{O})]$  such that  $\mathcal{O} \subseteq \mathcal{O}'$  and  $|\mathcal{O}| < k$ .

→Can we solve it approximately (with some guarantee) in polynomial time?

#### Overview

- 1. Definition of 'optimal' options for planning
- 2. The complexity of computing optimal options is NP-hard
- 3. Approximation algorithm for computing optimal options
- 4. Empirical evaluation to compare existing heuristic algorithms

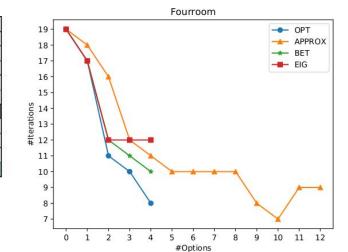

: Initiation State: *I*(s)

 $\blacksquare$  : Termination State:  $\beta$ (s)

(a) optimal k=2

(b) approx. k=2

## Assumptions

#### Task:

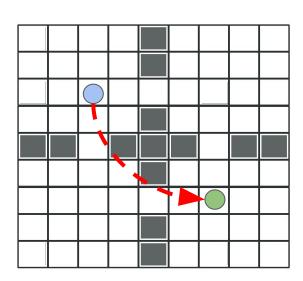

- Goal-based MDP: reach a goal while collecting maximum reward
- Maximum total reward is bounded

#### Options:

Point options

: Initiation State: I(s)

 $\blacksquare$ : Termination State:  $\beta(s)$ 

# Assumptions

#### The algorithms are not faster than solving the MDP itself

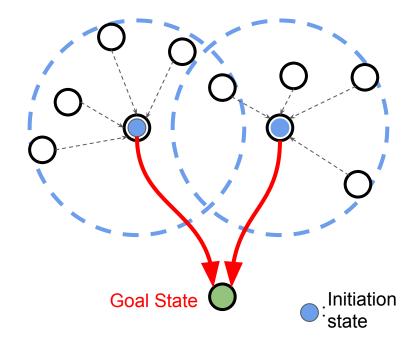

→The purpose of the algorithm is to analyze the quality of the heuristic algorithms, not for speeding up a single planning online

# Approximation Algorithm for MIMO

MIMO: Minimize L(O) subject to  $|O| \leq k$ 

#### Overview of the Algorithm:

- 1. Calculate the 'distance' between states
- 2. Reduce the asymmetric k-center problem based on the distance

# Approximation Algorithm for MIMO

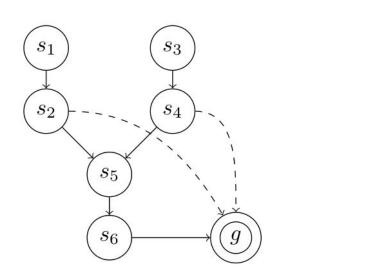

Theorem: The approximation algorithm has the following properties:

- The algorithm runs in polynomial time.
- 2. The algorithm gives the upper bound of the number of iterations required to solve the MDP using the option set
- 3. If the MDP is deterministic, the number of iterations is at most a factor of O(log\* k) times the minimum number of iterations, where k is the number of options allowed

# Approximation Algorithm for MOMI

MOMI: Minimize |O| subject to  $L(O) \leq L$ 

 $x_s$ : A set of states which can be solved within L steps if we add a point option from s to g

Example: 
$$L = 2$$

$$X_{s_1} = \{s_1\}$$
  
 $X_{s_2} = \{s_1, s_2\}$   
 $X_{s_3} = \{s_3\}$   
 $X_{s_4} = \{s_3, s_4\}$ 

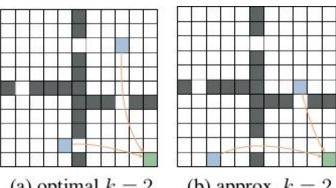

# Approximation Algorithm for MOMI

Theorem: The approximation algorithm has the following properties:

- 1. The algorithm runs in polynomial time.
- 2. The algorithm guarantees that the MDP is solved within the specified number of iterations using the acquired option set
- If the MDP is deterministic, the option set is at most a factor of O(log |S|) times larger than the smallest option set

#### Overview
